Abstract #000, March 19, 1999

Search for events with an isolated high energy lepton and missing transverse momentum at HERA

A search is performed for events with an imbalance in transverse momentum and with an isolated high energy lepton in e^-p scattering at HERA. The results are compared to those obtained from the e^+p HERA run where one e^- event and and five $\mu^\pm$ events were found together with evidence for unseen particles carrying tranverse momentum[1]. Three of the six events were found in a region of phase space likely to be populated by the production of W bosons with subsequent leptonic decay. The remaining three events showed kinematic properties which are atypical of all Standard Model processes considered.
